

Performance

How fast your site loads — and why people leave when it doesn't

People don't wait for slow websites. Three seconds is about all you get before someone hits the back button — and on mobile, even that might be generous. Speed isn't a nice-to-have, it's the difference between a visitor and a bounce.

Core Web Vitals

Google's set of performance metrics that actually affect your ranking. The main ones: how fast your main content appears, how quickly the page responds to a click, and whether things jump around while loading. You can score these for free in PageSpeed Insights.

Images Are Usually the Problem

I've looked at a lot of small business sites and unoptimized images are the culprit almost every time. A photo straight off a phone can be 5-10MB. The same image, properly compressed and converted to WebP, can be under 200KB with no visible quality difference.

Caching

When someone visits your site a second time, caching lets their browser load most of it from memory instead of re-downloading everything. Repeat visitors get a noticeably faster experience, which matters for customers who check back or share your link.

Your Host Matters

Cheap shared hosting puts your site on a server with hundreds of other sites competing for resources. When traffic spikes on any of them, yours slows down too. A proper host with a CDN serves your site from a location physically close to each visitor.

WHAT I HANDLE

Every image gets compressed and converted to WebP. Code gets minified. I'll also tell you straight up if your current host is holding your site back.
