

Security

The basics that keep your site from becoming someone else's problem

Small business sites get attacked constantly — not by people specifically targeting you, but by automated bots scanning the web for easy vulnerabilities. The good news is that most of these attacks exploit basic oversights that are completely preventable.

SSL / HTTPS

If your site still shows "Not Secure" in the browser, that's costing you visitors and rankings. SSL is free through most hosts and takes minutes to set up. There's no reason not to have it in 2026, and Google has been penalizing sites without it for years.

Contact Form Spam

An unprotected contact form will fill your inbox with garbage and can be used to send spam from your server. A basic CAPTCHA and server-side validation closes that off. It's not complicated — it just has to actually be done.

Keeping Things Updated

If your site runs on WordPress, outdated plugins are the #1 attack vector. Bots scan for known vulnerabilities in popular plugins and exploit them automatically. Staying current on updates isn't optional — it's maintenance.

Backups

If something goes wrong — a bad update, a hack, an accidental deletion — a recent backup means you're back up in an hour instead of starting over. Most good hosts include this automatically. If yours doesn't, that's worth knowing.

WHAT I SET UP

I set up SSL, form protection, and give you a checklist of what needs ongoing attention. I'll also flag any host-level gaps before they become your problem.
